

Elements of human language

Linear arrangement of words in a sentence...

W1 + W2 + W3 + W4 + W5

With very few exceptions (Japanese, Chinese and some other languages), most human languages arrange their words in linear order for the production of sentences.

This helps the natives to pronounce these elements of language easily.

It also defuses the Encoding/Decoding power into it as it becomes the part of the communication.

This is the only possible way to make one string of words different from others with regard to the meaning(s).¹

It is said that languages of the world would have been so naïve and simple if linear ordering were the only possibility for languages to arrange their elements.

The utterances could have been very short and simple and easy to understand and acquire.

Nevertheless, ideas expressed by this kind of language could have been limited.

Meaning, the function of human language could also have been very similar to that of many animal languages with regard to their forms and usages.

Thankfully, human languages have something very special as a feature and it is called 'constituent-ship' that non-human languages don't have.

And even if any non-human language has it, this feature is not as developed as it is in human languages.

Power of Constituent

Constituent-ship means that linguistic elements must 'group together' or 'merge' (Chomsky:1995) in discourse.

This is a fact that all language users unconsciously know about their mother tongue. (innateness hypothesis).

The process of 'grouping together' or 'merging' the linguistic elements into a higher unit can be done in several ways.

And each way is uniquely grounded in some method or principle which is similar across the board.

For example:

a. [good girls] and boys]] or [good[girls and boys]

Hierarchical Structure

HS means that the linguistic elements, having merged to one another or grouped together, must further 'nest' with one another like a spider web.

HS is very important as it makes human life easier and simpler.

This has been proven by psychological experiments as well as common sense that human mind can ONLY deal with a small number of things at a time.

The number of things, human mind can deal with at one time, has been suggested to 'from four to six' at the most (Payne 2006).

Take an example of a phone no. that reads as 9868608884.

Imagine that this is given to you when you did not have anything to write it down!!!!,

The question is, 'What would we do in such situation ?'

Some of the options are as follows:

- a. Repeat it many times, so that we remember it for a longer time, at least till the time when we can note it down somewhere.

This is an indication of an example of 'short-term memory to long/permanent memory' also know as 'over-learning'.

- b. According to our idiosyncratic style, we would unconsciously 'group' the phone no. into two, or more parts.

When we memorize these groups in a series like this, we convert the 'groups' into 'units' to ease our storage process in memory.

Once they become 'units', we group them again and again to make higher and higher units with some unique embedded structure.

Hierarchical Structure in languages is a natural consequence of the same fact of human cognition, where elements are grouped into parts and parts into units and units into bigger units and so forth ..

Rule governed/grammaticality

We saw that 'human language' is nothing but a matter of organizing the elements in different layers for the purpose of contextual retrieval.

And for such facilitation, every language has some or other 'conventionalized pattern or rules' that must be obeyed in terms of constructing linguistic elements into units.

Human mind seems to compartmentalize elements of language into different sets for the sake of comfortable retrieval of these elements at need.

The need is the context when we want different items/elements to group together to make communication possible.

In grouping the elements together human mind makes use of 'predictability' over randomness in terms of the possibility of occurrence of next element.

The entire world of CL/NLP/AI is based on these simple procedures of data mining!!

Before we get into the technicalities of the mechanism, let us see how linguistic elements work from single nucleus to a group and to the unit..

Elements of language:

Groups of elements:

Units of language

Higher Units of language

Different organizational levels

Words in linear order = word level

G.C. for Constituents = formal level

Subj; Obj & Verb = Notional level

Subj-Nom Obj-Acc = Categorical level

Agent; patient; theme = relational level

Linguistic elements higher than words

If we want to examine the linguistic elements responsible for the production of human communication for the level that is higher than a word, we must evaluate the ‘phrases’ and their processes of being formed.

Like a word(i.e. sound/group of sounds), a phrase can be made of either one word or a group of words.

When there is just one word to make a phrase, things are easy, however, when there is more than a word to form a phrase, we have to examine the ways in which these words are related to one another.

It is but necessary that one of words has to act **a head**, and others will be its dependents. (remember ‘endocentric principle’ from morphology class!!!)

This brings to us a very useful classification of linguistic elements as ‘head and dependent’.

If we know what a ‘head’ is, anything which is not ‘that’ will be dependents anyway..

Salient features of Head

- a. The grammatical category of head determines the GC of the entire phrase. For example:

1.
 - a. very bright [_N **sunflowers**]
 - b. [_V **overflowed**] quite quickly
 - c. very [_{Adj} **bright**]
 - d. quite [_{Adv} **quickly**]
 - e. [_P **inside**] the house

- b. The head must have the same 'distribution' as that of the phrase.

What does it mean to say 'distributional properties' of a lexical category?

For example, Noun is a lexical category and it can be the head of a phrase, so what are the distributional properties of a NOUN?

Distributional properties of a Noun

1. Noun, as a head word, should be able to occur at the subject and object_(s) places.
2. It must be modifiable by some modifiers (i.e. descriptive VS genitive)
3. It should be able to go through the process of pluralization.
4. An article must be able to make it definite/indefinite
5. It must be quantifiable
6. It should be able to take numeral modifiers as well.

Examples:

We could take any noun in English to exemplify these distributions of Noun, however, we will take a derived nominal, so that we talk some other complex issues later.

1. a. Swimming is good for you.

1.b. I like swimming.

2. a. I like reverse swimming.

2.b. This swimming is dangerous.

?3. Swimming(s) are easy in the swimming-pool.

4. The swimming in a flowing river is funny.

5. Every swimming is different.

6. I could not follow even one step of his swimming lesson.

C. It is not possible to omit/delete the 'head' from the phrase.

There are some rare situations where the head might be omitted, but it is either due to the economy of the speech in some context,

Or may be that the head has just been mentioned and then omitted. For example:

In answering the question 'Are you angry?', one can just say, 'very' but this is not the usual answer in English.

D. The 'head' obligatorily has to select its 'dependent(s)'.

This means that there may be some contexts where even the dependents to a head cannot be omitted or deleted. For example:

- a. The soldiers **released** the hostage.
- b. The soldiers **killed** the enemies.
- c. She lives **beside** the wood.
- d. She went **into** the building.

These examples show that the heads in bold have to select their respective dependents, and without these dependents the sentences would be ungrammatical.

The influence of the head on their dependents

1. *The heads select their dependent from a particular class.*

Thus, in English a head noun can be modified by an adjective but not by an adverb. For example

- a. *Bright sunflowers* is ok, but *brightly sunflowers* is not ok.
- b. In Kamera (Austronesian) language an adverb ‘*lalu*’, ‘too’ can modify a verb but not a noun.

a. lalu mbana-na na lodu
too hot-3sg the sun
‘The sun is too hot’.

b. * lalu lodu
too sun

2. Another influence that the ‘head’ of any phrase has on its dependents that it might require the dependents to **agree** with various grammatical features of the head.

One such grammatical feature is **grammatical gender** of the noun in NPs.

We know that not all languages make the distinction of the grammatical gender for every noun.

But in those where this distinction is made, the dependents to a head noun often display 'gender agreement' with the head.

Let us see the examples from French, Hindi and Punjabi

a. un livre vert b. une pomme verte
one-M book-3MS green-M one-F apple-3FS green-F
'One green book' 'One green apple'

a. sar-e lamb-e acc^h-e lark-e b. lambi-yā c^hangi-yā kuri-yā
all-Pl tall-M-Pl good-M-Pl boy-M-Pl tall-F-Pl beautiful-F-Pl girl-F-Pl
'All tall good boys' (Hindi) 'Beautiful tall girls'

3. In many languages, a head would want its dependents to occur in a particular grammatical case.

For example, in Japanese, in Hindi

a. kodomo-ga hon-o yon-da
child-Nom book-Acc read-pst
'The child read the book'.

Since the verb in the Japanese sentence is 'transitive' and thus will have two arguments; therefore two dependent NPs. These two NPs in Japanese must occur with Nominative and Accusative Case suffixes.

Let us examine the Hindi data:

a. bəcc^he-ne ma-ko dek^h-a
child-Erg mother-Acc see-3MS-pst
'The child saw (her) mother'.

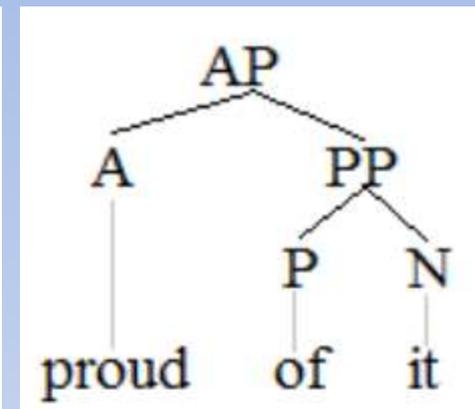

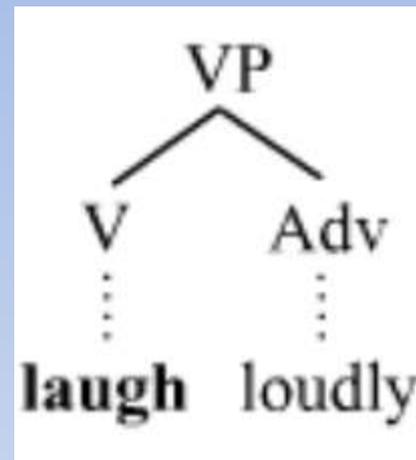

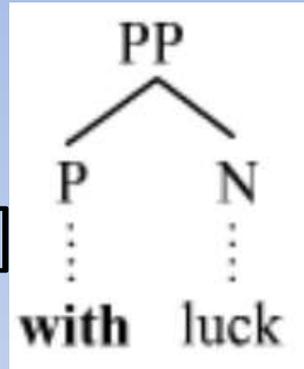

As we saw in case of Japanese, we see similar thing in the above example of Hindi,

The transitive verb of the clause which acts as the head for the sentential unification, and thus has taken two arguments; each of which bears the required grammatical cases i.e. Nominative (ergative) and accusative.

- Now let us evaluate the position of ‘head’ and ‘dependents’ available in a two-way system for the areal/typological classification of languages in the world.
- It has been discovered cross linguistically that there is a very strong tendency of placing the head and dependent in almost fixed position in different languages of the world.
- These two types are known as; **head-initial** VS **head-final**.
- A head-initial language would place its heads before the complements/dependents, while a head-final would do the reverse.
- 3/10/2018 Let us examine each of these systems:

Head-initial and Head-final languages :

- As we said the head in these languages would precede its complement/dependents. For example
- English:
 - [_{VP} **likes** chips]
 - [_{pp} **into** the water]
 - [_{AP} **fond** of chips]
 - [_{NP} **manufacturer** of tires]
- It is interesting to examine these sentences in English.
- The heads, **into** and **like** precede their complement NPs.
- And, the adjective head **fond**, and noun head **manufacturer** also precede their complement PP.
- Thus, English qualifies well for Head-Initial type.

- Welsh (Celtic language with VSO order) is a good example of head-initial language too.
- Let us examine how P as a head precedes the NP and the verb as a head precedes its complement NP (the direct object) in the following sentence.
- Welsh:

a. [_{PP} dros y ffordd]
 over the road

b. ddaru ceri [_{VP} yfed paned o de]
 did Ceri drink cupful of tea
 ‘Ceri drank a cup of tea’.

c. [_{GenP} paned of tea]
 cupful of tea

Tinrin (an Austronesian language SVO) also qualifies as the head-initial language.

The examples below will prove the fact where we will see the verb (head) occurs before the complement clause and the head noun also precedes its complement PP:

Tinrin:

a. u [VP tramwā mwā ke maija wake]
I know that you much work
'I know that you work hard'.

b. [NP kò rugi beebòrrò nrà mwiè]
news about drowning poss woman
'The news of the woman's drowning'.

- ‘**Head-final**’ languages, on the other hand, would be the ones in which the head follows the complements/dependents.
- Different kinds of structure of phrases in Japanese, Turkish and Hindi would exemplify the concept of ‘Head-final’:
- Japanese:

a. taro-ga [VP tana-ni hon-o **oita**]
Tora-Nom shelf-Loc book-Acc put
‘Tora put the book on the shelf’.

b. [PP tomodati-to]
friend -with

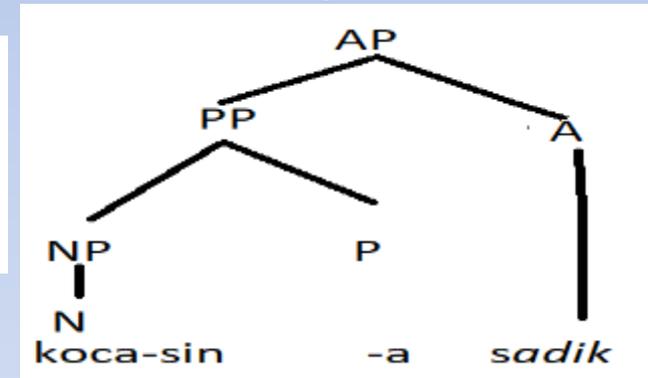

c. [NP sono esuto e no **zisin**]
that test to poss confidence
‘Confidence in that test’

In the above Japanese example (a), the verb is the head and the verb occurs at the end of the sentence, and other two dependents (complements) **shelf** and **table** precede the head word i.e. the verb.

Similarly in (b), the head is the postposition and it occurs after the complement NP.

Finally, the head noun follows its complements in example (c). Turkish is another 'head-final' language. Let's see the expl:

a. [AP koca-sin-a sadik]
husband-3S-Dat loyal
'loyal to her husband'

As we see in the above Turkish example, the complements of this adjective occur before the head word 'sadik' which occurs as the final word in the phrase, and also the PP that marks the 'dative' is also the head of the PP which occurs on the right side of its complement.
